1 ABSTRACT

2	A method for detecting surveillance activity in a computer communication network
3	comprising automatic detection of malicious probes and scans and adaptive learning.
4	Automatic scan / probe detection in turn comprises modeling network connections, detecting
5	connections that are likely probes originating from malicious sources, and detecting scanning
6	activity by grouping source addresses that are logically close to one another and by
7	recognizing certain combinations of probes. The method is implemented in a scan/probe
. 8	detector, preferably in combination with a commercial or open-source intrusion detection
9	system and an anomaly detector. Once generated, the model monitors online activity to
10	detect malicious behavior without any requirement for a priori knowledge of system
11	behavior. This is referred to as "behavior-based" or "mining-based detection." The three main
12	components may be used separately or in combination with each other. The alerts produced
13	by each may be presented to an analyst, used for generating reports (such as trend analysis),
14	or correlated with alerts from other detectors. Through correlation, the invention prioritizes
15	alerts, reduces the number of alerts presented to an analyst, and determines the most
16	important alerts.
